## **International Center for Public Policy Andrew Young School of Policy Studies**

The Andrew Young School of Policy Studies was established at Georgia State University with the objective of promoting excellence in the design, implementation, and evaluation of public policy. In addition to four academic departments, including economics and public administration, the Andrew Young School houses eight leading research centers and policy programs, including the International Center for Public Policy.

The mission of the International Center for Public Policy (ICePP) at the Andrew Young School of Policy Studies is to provide academic and professional training, applied research, and technical assistance in support of sound public policy and sustainable economic growth in developing and transitional economies.

ICePP is recognized worldwide for its efforts in support of economic and public policy reforms through technical assistance and training around the world. This reputation has been built serving a diverse client base, including the World Bank, the U.S. Agency for International Development (USAID), the United Nations Development Programme (UNDP), finance ministries, government organizations, legislative bodies, and private sector institutions.

The success of ICePP reflects the breadth and depth of its in-house technical expertise. The Andrew Young School's faculty are leading experts in economics and public policy and have authored books, published in major academic and technical journals, and have extensive experience in designing and implementing technical assistance and training programs. Andrew Young School faculty have been active in policy reform in over 40 countries around the world. Our technical assistance strategy is not merely to provide technical prescriptions for policy reform, but to engage in a collaborative effort with host governments and donor agencies to identify and analyze the issues at hand, arrive at policy solutions, and implement reforms.

ICePP specializes in four broad policy areas:

- Fiscal policy (e.g., tax reforms, public expenditure reviews)
- Fiscal decentralization (e.g., reform, intergovernmental transfer systems, urban finance)
- Budgeting and fiscal management (e.g., local, performance-based, capital, and multi-year budgeting)
- Economic analysis and revenue forecasting (e.g., micro-simulation, time series forecasting)

*For more information about our technical assistance activities and training programs, please visit our website at [icepp.gsu.edu](http://icepp.gsu.edu) or contact us at [paulbenson@gsu.edu](mailto:paulbenson@gsu.edu).*

# Systemic Financial Crises and Income Inequality in OECD Countries

Puneet Arora, Alberto Chong and Carla Srebot<sup>1</sup>

August 2023

## Abstract

We offer a theory and evidence that support the view that systemic financial crises impact income inequality negatively in richer countries, where institutions such as social safety nets work better than in developing countries. More generally, to our knowledge, our work is the first to provide empirical evidence that supports the view that systemic financial crises may have a causal impact on income inequality and that a driving mechanism may be vulnerable employment. In order to do this, we apply a difference-in-difference approach and provide evidence that the parallel trends assumption is complied with.

**Keywords:** bank runs, systemic crisis; inequality; OECD

**JEL Classification:** E0, G0, O0

## Introduction

It is believed that systemic financial crises produce devastating impacts on the economy, not only reflected in slower rates of growth and high interest rates, but equally important, via protracted and pervasive negative effect in living standards and overall welfare of a significant part of the population. This is because the resources committed to resolving a crisis may be diverted from alternative productive uses, delaying structural economic reforms as well as stabilization programs. Moreover, the economy may see higher unemployment rates for a protracted period, which in turn may be translated to structural increases in income inequality and, depending on the depth of the crisis, may become quite pervasive (e.g., Čihák and Sahay, 2020).

According to conventional wisdom, richer countries are better positioned to deal with systemic financial crises due to their stronger institutions, which may help governments contain any negative impacts that may arise due to productive and distributive misallocations resulting from a crisis. Richer economies tend to have more expansive options—such as unemployment insurance, job-retraining, and poverty-fighting mechanisms—and, in general, more widespread and deep social safety nets. A question that remains unanswered is whether countries with good institutions, typically the richer economies, are actually able to withstand systemic financial shocks and minimize welfare related impacts and, in particular, a decrease in income inequality, a variable of particular concern by policymakers and academics alike. In fact, to our knowledge, our work is the first to provide empirical evidence that supports the view that systemic financial crises may have a causal impact on income inequality.<sup>1</sup>

---

<sup>1</sup> A systemic financial crisis is defined as financial runs that lead to the closure, merging, or takeover by the public sector of one or more financial institutions.

## Simple Theoretical Model

Our theory links the effect of a systemic crisis on income inequality through its impact on vulnerable employment, which is proxied by an increase in the variance of an economy's skills distribution.<sup>2</sup> In order to do this, we extend Chong and Gradstein (2007) and assume that the economy is populated by households that sum to a measure of 1. Each household  $i$  is populated by a parent and a child, with parent being the sole decision-maker in discrete time  $t$ .  $y_{i0}$  is household  $i$ 's exogenously given initial income in period 0, and  $y_{it}$  is household  $i$ 's endogenously determined income in period  $t$ , with  $y_{it} \sim \text{lognormal}(\mu_t, \sigma_t^2)$ . Household  $i$ 's budget constraint is given by:

$$y_{it} = c_{it} + r_{it+1} \quad (1)$$

where prices are normalized to 1,  $c_{it} \geq 0$  is household  $i$ 's current consumption (which also includes productive investment in skills) and  $r_{it+1} \geq 0$  is their unproductive investment in rent seeking. Based on Chong and Gradstein (2007) we assume that  $A > 0$  is the economy's total productive resources and is constant in every period  $t$ . The proportion of  $A$  that accrues to household  $i$  is given by:

$$a_{it+1}^{w_{t+1}} = A \frac{r_{it+1}^{w_{t+1}}}{\int_0^1 r_{it+1}^{w_{t+1}} di} \quad (2)$$

where  $w_{t+1} \in [0, 1]$  is the institutional quality and  $r_{it+1}^{w_{t+1}}$  is the rent-seeking investment. Our interest is on the case when  $w_{t+1}$  is close to 0, that is, economies with strong institutions.<sup>3</sup>

Household  $i$ 's income in period  $t$ ,  $y_{it}$ , is determined by:

---

<sup>2</sup> Vulnerable employment refers to those that are less likely to have formal work arrangements, inadequate earnings, lack decent working conditions, adequate social security and effective representation (World Bank, 2021).

<sup>3</sup>  $w_{t+1}$  close to 1 implies weak institutions.

$$y_{it} = \varepsilon_{it} a_{it}^{w_t} \quad (3)$$

where  $\varepsilon_{it}$  are household  $i$ 's productive skills,  $\varepsilon_{it} \sim \text{lognormal}(0, \gamma^2)$ , with  $\gamma^2$  assumed to be small, and  $a_{it}^{w_t}$  are household  $i$ 's appropriated resources. Individuals who are at the left tail of productive skills distribution represent vulnerable employment, as evidence shows that economic crisis adversely impacts the latter (e.g., Oulton and Barriol, 2017). We proxy this impact with an increase in the variance of the skill distribution, represented by the shape parameter,  $\gamma^2$ . Household  $i$  optimizes the following symmetric utility function in time  $t$ :

$$V(c_{it}, y_{it+1}) = \ln(c_{it}) + \ln(y_{it+1}) \quad (4)$$

The optimal budget allocation rules for individual  $i$  are as follows:

$$c_{it} = y_{it} \frac{1}{1+w_{t+1}}, r_{it+1} = y_{it} \frac{w_{t+1}}{1+w_{t+1}} \quad (5)$$

with the evolution of income rule as follows:

$$y_{it+1} = \varepsilon_{it+1} A \frac{y_{it}^{w_{t+1}}}{\int_0^1 y_{it}^{w_{t+1}} di} \quad (6)$$

Taking logs in (6), the evolution of income inequality equation is:

$$\sigma_{t+1}^2 - \sigma_t^2 = \gamma^2 + \sigma_t^2(w_{t+1} - 1) \quad (7)$$

With strong institutions,  $w_{t+1} = 0$ , inequality will fall and converge to a constant,  $\gamma^2$ . Following (7) inequality will converge to the following steady state:

$$\sigma^{2*} = \frac{\gamma^2}{1-w} > \gamma^2 \quad (8)$$

Consider the scenario when this economy experiences a situation of economic crisis in period  $t$ . This gives an exogenous shock to the skills distribution affecting people in vulnerable employment

more, thus increasing the shape parameter (and variance), such that  $\varepsilon_{it} \sim \text{lognormal}(0, \gamma'^2)$  with  $\gamma' > \gamma$ .<sup>4</sup> From equation (7), we can conclude that inequality will converge to the new constant,  $\gamma'^2$ . Thus, an economic crisis increases the base level of income inequality to a higher level. When institutions are strong, income inequality remains constant every period at this new base level.<sup>5</sup> It follows that a systemic crisis changes the steady state level of income inequality to:

$$\sigma'^2 = \frac{\gamma'^2}{1-w} > \sigma^2 \quad (8')$$

In short, according to our simple extension of Chong and Gradstein (2007), an economic crisis increases the likelihood of occurrence of the steady state with higher inequality.

### Data and Empirical Strategy

Our data are all publicly available and come from the World Bank (2021) and United Nations (2021) and focus on OECD countries as, on average, these are the group of countries that have shown stronger institutions from a historical perspective. Our key variable of interest is income inequality, which we capture using the well-known Gini coefficient, an index that goes from zero to one and where higher numbers indicate higher income inequality. We also include time-varying covariates at the country level—in particular, the GDP growth, the log of per capita GDP, and the years that a country has suffered from a systemic financial crisis since 1970.<sup>6</sup> Our

---

<sup>4</sup> Such a shock would also affect the scale parameter of the log-normal skills distribution. However, qualitatively the results will move in the same direction as with change in the shape parameter. For simplicity, we do not discuss the changes in scale parameter in our model.

<sup>5</sup> If institutions are weak, i.e.,  $w+1-w > 0$ , inequality will always be greater than  $\gamma'^2$ , and with  $\gamma'^2$  moderately high, inequality would continue to increase at a rate higher than the rate without an economic crisis,  $\gamma'^2 - \gamma'^2 + \gamma'^2 w - \gamma'^2 w > \gamma'^2 + \gamma'^2 w - \gamma'^2 w > 0$ . When institutions are weak and existing inequality is moderately high, economic crisis also increases the likelihood that the economy experiences an increase in inequality every period.

<sup>6</sup> The countries in our sample, including the first year of crisis in parentheses, are: Belgium (2008), Chile (1976), Denmark (2008), Finland (1991), Germany (2007), Greece (2008), Iceland (2007), Ireland (2007), Italy (2008), Japan (1997), Korea (1997), Mexico (1981), Netherlands (2008), Norway (1987), Poland (1991), Spain (1977),

period of study covers the years 1973 to 2016. Table 1 presents summary statistics. Methodologically, we estimate the following equation:

$$y_{ct} = \beta_0 + \beta_1 SC_{ct} + X_{ct}\beta_2 + \gamma_c + \lambda_t + \varepsilon_{ct} \quad (1)$$

where  $y_{ct}$  denotes an inequality indicator in country  $c$  in year  $t$ , where  $SC_{ct}$  is an indicator equal to one if country  $c$  had a systemic crisis prior year  $t$ ,  $X$  is the set of country-level covariates described above, and  $\gamma_c$ ,  $\lambda_t$  are country and year fixed effects, respectively. We test for the critical parallel pre-trend assumptions by the specification:

$$y_{ct} = \beta_0 + \sum_{k=-7}^7 \vartheta_k \tau_{ctk} + X_{ct}\beta_2 + \gamma_c + \lambda_t + \varepsilon_{ct} \quad (2)$$

where  $\tau_{ctk}$  takes a value equal to 1 when an observation is  $k$  years away from the year the first systemic financial crisis struck. We normalize all estimates to the year before the first crisis occurred by omitting  $k = 1$ . Note that  $k$  equal to  $-7$  or  $7$  denotes more than six years before and after crises.

## Findings

Table 2 shows our main empirical results. The estimated coefficient of systemic financial crises on income inequality, as measured by the Gini coefficient, indicates that systemic crises do increase income inequality, reflected in the fact that the coefficient of our variable of interest is positive and statistically significant at conventional levels.<sup>7</sup> Our preferred specification is the one shown in Column 4, which also includes year fixed effects, country fixed effects, as well as

---

Sweden (1991) and Turkey (1982). Excluding Chile and Mexico, the two newest OECD members, which are also considered to be the ones with relatively weakest institutions, do not change our findings.

<sup>7</sup> While not reported, these results are very robust to broad changes in specification.

standard errors clustered at the country level. As taxing as this specification is, the statistical significance of our variable of interest holds at conventional levels.<sup>8</sup>

For our difference-in-differences strategy to be valid, we show the results of specification (2) above. Countries that suffer from systemic financial crises must show similar inequality trends as countries that do not suffer from systemic crises. This is the so-called common trends assumption. Finding this implies that systemic crises are not driven by confounding trends in unobserved factors that systematically affect income inequality. Figure 1 reports our findings for the Gini coefficient. As observed in this figure, trends in the pre-event period are flat and indistinguishable from zero, thus providing support on the common trend assumption. In addition, Figure 1 shows that the negative impact of systemic crises on income inequality persist in subsequent years after they occur.

Using the same approach as above, we test whether a likely mediating mechanism between crises and inequality may be vulnerable employment. As shown in Figure 2, we find supporting evidence that this may be the case. Pre-systemic shock, the behavior of this variable is very clear. The coefficient of vulnerable employment is zero; however, post-systemic shock, this variable sees a dramatic and steady increase in its coefficient, which is statistically significant at conventional levels and lasts for at least six periods subsequent to the first occurrence of the first systemic shock.

---

<sup>8</sup> Callaway and Sant'Anna (2021) have very recently raised some issues related to the application of staggered differences-in-differences. Unfortunately, our data does not have enough observations with the requirements needed in order to apply such test correctly, and as a result, we are unable to rule out the issue raised by these researchers.

## Final Remarks

Some researchers claim that the direction of causality between financial crisis and income inequality may go from inequality to banking crises. Among others, Rajan (2010) describes a scenario where inequality may create pressure for easy credit and where the financial sector provides unequal access to education and health care, which may increase the risk for financial crisis. Recent research, however, cast very serious doubts on the existence of a causal link from income inequality to financial crises (e.g., Bordo and Meissner, 2012).<sup>9</sup> Whereas our findings appear to be very robust, we agree that statistically speaking we cannot fully rule out other sources of endogeneity that might weaken our findings. Additional research is needed in this regard.
